Lab Exercise1a
(Chapter One)

1. Develop a function-based C++ program that read an integer number and find the square, if it is -ve and otherwise square root. The function should be declared and defined in a sperate file, it should accept the number as a parameter and return a value (either the square or the square root). The function should be called in a file where the main function is written.

2. Write a program function-based program that read the two sides of right-angle triangle and find the length of the third side. The function accepts the two sides as a parameter by value and third side by reference and print inside main function.

3. Write a program that print the **right-angle triangle** pattern of minimum length 5 using '*' as a default symbols. The program should prompt the user to choose either to print default pattern or enter his/her own by entering different symbol and size.

4. Write a function-based C++ program that find the **Fibonacci series** of a given number. Define a function named **Fibonacci** that has one argument with default argument and returns integer. The function is called both with parameter and without parameter. (do the problem again using recursive function)

5. Write a c++ program using recursive function to reverse a number with two or more digits. (e.g 123 to 321)
